There are many types of foam-injection molding machines that are known in the art. The various existing machines have a number of shortcomings. For example, the existing machines typically employ a mold having a gate having an opening in it. One problem with the gate configuration is that the gate allows molding material to escape. Also, opening the mold causes delays in molding processes. Thus, the gate configurations of existing machines contribute to production delays. In addition, some existing machines are not equipped to handle large size molds and can only be used in conjunction with a mold having a limited number of gate configurations, thereby restricting the machine user's design options. Another shortcoming of existing machines is that they do not provide efficient uniform distribution of injected molding

material to the mold cavities. In this regard, the mold cavities are placed at select locations within the mold cavity volume. The select locations in existing machines do not provide a full range of potential injection positions. Thus, the mold cavities in the existing machines are not dispersed evenly, which in turn limits the efficiency of existing machines and their ability to provide uniform molding products. Another shortcoming of existing machines is that the molding cavities in the existing machines are equipped with either a single-cast coil, or a few cast coils, and thus the cavities are not dispersed evenly. Thus, the single-cast
